## 4.3 Pin Multiplexing

Pin multiplexing for these devices is controlled by both register settings and operating modes (for example, if the device is in test mode). For details of the settings for each pin and diagrams of the multiplexed ports, see [§ 6.11.24](#).

## 4.4 Connection of Unused Pins

[Table 4-3](#) lists the correct termination of all unused pins.

**Table 4-3. Connection of Unused Pins<sup>(1)</sup>**

PIN	POTENTIAL	COMMENT
AVCC	DV <sub>CC</sub>	
AVSS	DV <sub>SS</sub>	
Px.0 to Px.7	Open	Set to port function, output direction (PxDIR.n = 1)
R33/LCDCAP	DV <sub>SS</sub> or DV <sub>CC</sub>	If the pin is not used, it can be tied to either supply.
ESIDVCC	DV <sub>CC</sub>	
ESIDVSS	DV <sub>SS</sub>

$\overline{\text{RST}}/\text{NMI}$	DV <sub>CC</sub> or V <sub>CC</sub>	47-k $\Omega$ pullup or internal pullup selected with 2.2-nF (10-nF <sup>(2)</sup> ) pulldown
PJ.0/TDO PJ.1/TDI PJ.2/TMS PJ.3/TCK	Open	The JTAG pins are shared with general-purpose I/O function (PJ.x). If not used as JTAG pins, these pins should be switched to port function, output direction. When used as JTAG pins, these pins should remain open.
TEST	Open	This pin always has an internal pulldown enabled.

- (1) Any unused pin with a secondary function that is shared with general-purpose I/O should follow the Px.0 to Px.7 unused pin connection guidelines.
- (2) The pulldown capacitor should not exceed 2.2 nF when using devices in Spy-Bi-Wire mode or in 4-wire JTAG mode with TI tools like FET interfaces or GANG programmers. If JTAG or Spy-Bi-Wire access is not needed, up to a 10-nF pulldown capacitor may be used.

## 5 Specifications

### 5.1 Absolute Maximum Ratings<sup>(1)</sup>

over operating free-air temperature range (unless otherwise noted)

	MIN	MAX	UNIT
Voltage applied at DVCC and AVCC pins to V <sub>SS</sub>	−0.3	4.1	V
Voltage difference between DVCC and AVCC pins <sup>(2)</sup>		±0.3	V
Voltage applied to any pin <sup>(3)</sup>	−0.3	V <sub>CC</sub> + 0.3 V (4.1 Max)	V
Diode current at any device pin		±2	mA
Storage temperature, T <sub>stg</sub> <sup>(4)</sup>	−40	125	°C

- (1) Stresses beyond those listed under *Absolute Maximum Ratings* may cause permanent damage to the device. These are stress ratings only, and functional operation of the device at these or any other conditions beyond those indicated under *Recommended Operating Conditions* is not implied. Exposure to absolute-maximum-rated conditions for extended periods may affect device reliability.
- (2) Voltage differences between DVCC and AVCC exceeding the specified limits may cause malfunction of the device including erroneous writes to RAM and FRAM.
- (3) All voltages referenced to V<sub>SS</sub>.
- (4) Higher temperature may be applied during board soldering according to the current JEDEC J-STD-020 specification with peak reflow temperatures not higher than classified on the device label on the shipping boxes or reels.

### 5.2 ESD Ratings

		VALUE	UNIT
V <sub>(ESD)</sub> Electrostatic discharge	Human-body model (HBM), per ANSI/ESDA/JEDEC JS-001 <sup>(1)</sup>	±1000	V
	Charged-device model (CDM), per JEDEC specification JESD22-C101 <sup>(2)</sup>	±250	

- (1) JEDEC document JEP155 states that 500-V HBM allows safe manufacturing with a standard ESD control process. Pins listed as ±1000 V may actually have higher performance.
- (2) JEDEC document JEP157 states that 250-V CDM allows safe manufacturing with a standard ESD control process. Pins listed as ±250 V may actually have higher performance.

### 5.3 Recommended Operating Conditions

Typical data are based on V<sub>CC</sub> = 3.0 V, T<sub>A</sub> = 25°C unless otherwise noted.

		MIN	NOM	MAX	UNIT
V <sub>CC</sub>	Supply voltage range applied at all DVCC, AVCC, and ESIDVCC pins <sup>(1) (2) (3)</sup>	1.8 <sup>(4)</sup>		3.6	V
V <sub>SS</sub>	Supply voltage applied at all DVSS, AVSS, and ESIDVSS pins		0		V
T <sub>A</sub>	Operating free-air temperature	−40		85	°C
T <sub>J</sub>	Operating junction temperature	−40		85	°C
C <sub>DVCC</sub>	Capacitor value at DVCC and ESIDVCC <sup>(5)</sup>	1–20%			μF
f <sub>SYSTEM</sub>	Processor frequency (maximum MCLK frequency) <sup>(6)</sup>	No FRAM wait states (NWAITSx = 0)		8 <sup>(7)</sup>	MHz
		With FRAM wait states (NWAITSx = 1) <sup>(8)</sup>		16 <sup>(9)</sup>	
f <sub>ACLK</sub>	Maximum ACLK frequency			50	kHz
f <sub>SMCLK</sub>	Maximum SMCLK frequency			16 <sup>(9)</sup>	MHz

- (1) TI recommends powering the DVCC, AVCC, and ESIDVCC pins from the same source. At a minimum, during power up, power down, and device operation, the voltage difference between DVCC, AVCC, and ESIDVCC must not exceed the limits specified in [Absolute Maximum Ratings](#). Exceeding the specified limits may cause malfunction of the device including erroneous writes to RAM and FRAM.
- (2) See [Table 5-1](#) for additional important information.
- (3) Modules may have a different supply voltage range specification. See the specification of each module in this data sheet.
- (4) The minimum supply voltage is defined by the supervisor SVS levels. See [Table 5-2](#) for the exact values.
- (5) Connect a low-ESR capacitor with at least the value specified and a maximum tolerance of 20% as close as possible to the DVCC and ESIDVCC pins.
- (6) Modules may have a different maximum input clock specification. See the specification of each module in this data sheet.
- (7) DCO settings and HF crystals with a typical value less than or equal to the specified MAX value are permitted.
- (8) Wait states only occur on actual FRAM accesses; that is, on FRAM cache misses. RAM and peripheral accesses are always executed without wait states.
- (9) DCO settings and HF crystals with a typical value less than or equal to the specified MAX value are permitted. If a clock sources with a larger typical value is used, the clock must be divided in the clock system.

(1) All inputs are tied to 0 V or to  $V_{CC}$ . Outputs do not source or sink any current.

(2) Characterized with program executing typical data processing.

$f_{ACLK} = 32768$  Hz,  $f_{MCLK} = f_{SMCLK} = f_{DCO}$  at specified frequency, except for 12 MHz. For 12 MHz,  $f_{DCO} = 24$  MHz and  $f_{MCLK} = f_{SMCLK} = f_{DCO} / 2$ .

At MCLK frequencies above 8 MHz, the FRAM requires wait states. When wait states are required, the effective MCLK frequency ( $f_{MCLK,eff}$ ) decreases. The effective MCLK frequency also depends on the cache hit ratio. SMCLK is not affected by the number of wait states or the cache hit ratio.

The following equation can be used to compute  $f_{MCLK,eff}$ :

$$f_{MCLK,eff} = f_{MCLK} / [\text{wait states} \times (1 - \text{cache hit ratio}) + 1]$$

For example, with 1 wait state and 75% cache hit ratio  $f_{MCLK,eff} = f_{MCLK} / [1 \times (1 - 0.75) + 1] = f_{MCLK} / 1.25$ .

(3) Represents typical program execution. Program and data reside entirely in FRAM. All execution is from FRAM.

(4) Program resides in FRAM. Data resides in SRAM. Average current dissipation varies with cache hit-to-miss ratio as specified. Cache hit ratio represents number cache accesses divided by the total number of FRAM accesses. For example, a 75% ratio implies three of every four accesses is from cache, and the remaining are FRAM accesses.

(5) See Figure 5-1 for typical curves. Each characteristic equation shown in the graph is computed using the least squares method for best linear fit using the typical data shown in Section 5.4.

(6) Program and data reside entirely in RAM. All execution is from RAM.

(7) Program and data reside entirely in RAM. All execution is from RAM. FRAM is off.

## 5.5 Typical Characteristics, Active Mode Supply Currents

I(AM, cache hit ratio): Program resides in FRAM. Data resides in SRAM. Average current dissipation varies with cache hit-to-miss ratio as specified. Cache hit ratio represents number cache accesses divided by the total number of FRAM accesses. For example, a 75% ratio implies three of every four accesses is from cache, and the remaining are FRAM accesses.

I(AM, RAMonly): Program and data reside entirely in RAM. All execution is from RAM. FRAM is off.

## 5.13 Timing and Switching Characteristics

### 5.13.1 Power Supply Sequencing

TI recommends powering the AVCC, DVCC, and ESIDVCC pins from the same source. At a minimum, during power up, power down, and device operation, the voltage difference between AVCC, DVCC, and ESIDVCC must not exceed the limits specified in [Absolute Maximum Ratings](#). Exceeding the specified limits may cause malfunction of the device including erroneous writes to RAM and FRAM.

At power up, the device does not start executing code before the supply voltage reached  $V_{SVSH+}$  if the supply rises monotonically to this level.

表 5-1 lists the power ramp requirements.

表 5-1. Brownout and Device Reset Power Ramp Requirements

over recommended ranges of supply voltage and operating free-air temperature (unless otherwise noted)

PARAMETER	TEST CONDITIONS	MIN	MAX	UNIT
$V_{VCC\_BOR-}$ Brownout power-down level <sup>(1)(2)</sup>	$ dV_{CC}/dt  < 3 \text{ V/s}^{(3)}$	0.7	1.66	V
	$ dV_{CC}/dt  > 300 \text{ V/s}^{(3)}$	0		
$V_{VCC\_BOR+}$ Brownout power-up level <sup>(2)</sup>	$ dV_{CC}/dt  < 3 \text{ V/s}^{(4)}$	0.79	1.68	V

- (1) In case of a supply voltage brownout, the device supply voltages must ramp down to the specified brownout power-down level ( $V_{VCC\_BOR-}$ ) before the voltage is ramped up again to ensure a reliable device start-up and performance according to the data sheet including the correct operation of the on-chip SVS module.
- (2) Fast supply voltage changes can trigger a BOR reset even within the recommended supply voltage range. To avoid unwanted BOR resets, the supply voltage must change by less than 0.05 V per microsecond ( $\pm 0.05 \text{ V}/\mu\text{s}$ ). Following the data sheet recommendation for capacitor  $C_{DVCC}$  should limit the slopes accordingly.
- (3) The brownout levels are measured with a slowly changing supply. With faster slopes, the MIN level required to reset the device properly can decrease to 0 V. Use the graph in 图 5-6 to estimate the  $V_{VCC\_BOR-}$  level based on the down slope of the supply voltage. After removing  $V_{CC}$ , the down slope can be estimated based on the current consumption and the capacitance on DVCC:  $dV/dt = I/C$  where  $dV/dt = \text{slope}$ ,  $I = \text{current}$ ,  $C = \text{capacitance}$ .
- (4) The brownout levels are measured with a slowly changing supply.

- (1) To improve EMI on the LFXT oscillator, observe the following guidelines.
  - Keep the trace between the device and the crystal as short as possible.
  - Design a good ground plane around the oscillator pins.
  - Prevent crosstalk from other clock or data lines into oscillator pins LFXIN and LFXOUT.
  - Avoid running PCB traces underneath or adjacent to the LFXIN and LFXOUT pins.
  - Use assembly materials and processes that avoid any parasitic load on the oscillator LFXIN and LFXOUT pins.
  - If conformal coating is used, ensure that it does not induce capacitive or resistive leakage between the oscillator pins.
- (2) When LFXTBYPASS is set, LFXT circuits are automatically powered down. Input signal is a digital square wave with parametrics defined in the Schmitt-trigger Inputs section of this data sheet. Duty cycle requirements are defined by  $DC_{LFXT, SW}$ .

- (4) Oscillation allowance is based on a safety factor of 5 for recommended crystals. The oscillation allowance is a function of the LFXTDRIVE settings and the effective load. In general, comparable oscillator allowance can be achieved based on the following guidelines, but should be evaluated based on the actual crystal selected for the application:
- For LFXTDRIVE = {0}, C<sub>L,eff</sub> = 3.7 pF.
  - For LFXTDRIVE = {1}, C<sub>L,eff</sub> = 6 pF
  - For LFXTDRIVE = {2}, 6 pF ≤ C<sub>L,eff</sub> ≤ 9 pF
  - For LFXTDRIVE = {3}, 9 pF ≤ C<sub>L,eff</sub> ≤ 12.5 pF
- (5) This represents all the parasitic capacitance present at the LFXIN and LFXOUT terminals, respectively, including parasitic bond and package capacitance. The effective load capacitance, C<sub>L,eff</sub> can be computed as C<sub>IN</sub> × C<sub>OUT</sub> / (C<sub>IN</sub> + C<sub>OUT</sub>), where C<sub>IN</sub> and C<sub>OUT</sub> are the total capacitance at the LFXIN and LFXOUT terminals, respectively.
- (6) Requires external capacitors at both terminals to meet the effective load capacitance specified by crystal manufacturers. Recommended effective load capacitance values supported are 3.7 pF, 6 pF, 9 pF, and 12.5 pF. Maximum shunt capacitance of 1.6 pF. The PCB adds additional capacitance, so it must also be considered in the overall capacitance. Verify that the recommended effective load capacitance of the selected crystal is met.
- (7) Includes start-up counter of 1024 clock cycles.

(1) Internal reference noise affects ADC performance when ADC uses internal reference. See [Designing With the MSP430FR59xx and MSP430FR58xx ADC](#) for details on optimizing ADC performance for your application with the choice of internal versus external reference.

(2) Buffer offset affects ADC gain error and thus total unadjusted error.

(3) The internal reference current is supplied through terminal AVCC.

(4) Calculated using the box method: (MAX(–40°C to 85°C) – MIN(–40°C to 85°C)) / MIN(–40°C to 85°C) / (85°C – (–40°C)).

(5) The condition is that the error in a conversion started after t<sub>REFON</sub> is less than ±0.5 LSB.

## 6 Detailed Description

### 6.1 Overview

The TI MSP430FR698x and MSP430FR598x families of ultra-low-power microcontrollers consists of several devices featuring different sets of peripherals. The architecture, combined with seven low-power modes, is optimized to achieve extended battery life for example in flow metering applications. The devices features a powerful 16-bit RISC CPU, 16-bit registers, and constant generators that contribute to maximum code efficiency.

The MSP430FR698x and MSP430FR598x devices are microcontroller configurations with an extended scan interface (ESI) for background water, heat and gas volume metering together with up to five 16-bit timers, a comparator, eUSCs that support UART, SPI, and I<sup>2</sup>C, a hardware multiplier, an AES accelerator, DMA, an RTC module with alarm capabilities, up to 83 I/O pins, and a high-performance 12-bit ADC. The MSP430FR698x devices also include an LCD module with contrast control for displays with up to 320 segments.

### 6.2 CPU

The MSP430 CPU has a 16-bit RISC architecture that is highly transparent to the application. All operations, other than program-flow instructions, are performed as register operations in conjunction with seven addressing modes for source operand and four addressing modes for destination operand.

The CPU is integrated with 16 registers that provide reduced instruction execution time. The register-to-register operation execution time is one cycle of the CPU clock.

Four of the registers, R0 to R3, are dedicated as program counter, stack pointer, status register, and constant generator, respectively. The remaining registers are general-purpose registers.

Peripherals are connected to the CPU using data, address, and control buses. Peripherals can be managed with all instructions.

The instruction set consists of the original 51 instructions with three formats and seven address modes and additional instructions for the expanded address range. Each instruction can operate on word and byte data.

## 6.3 Operating Modes

The MSP430FR698x(1) and MSP430FR598x(1) MCUs have one active mode and seven software selectable low-power modes of operation (see 表 6-1). An interrupt event can wake up the device from a low-power mode (LPM0 to LPM4), service the request, and restore back to the low-power mode on return from the interrupt program. Low-power modes LPM3.5 and LPM4.5 disable the core supply to minimize power consumption.

表 6-1. Operating Modes

(1) FRAM disabled in FRAM controller

(2) Disabling the FRAM through the FRAM controller decreases the LPM current consumption, but the wake-up time can increase. If the wake-up is for FRAM access (for example, to fetch an interrupt vector), wake-up time is increased. If the wake-up is for an operation other than FRAM access (for example, DMA transfer to RAM), wake-up time is not increased.

(3) All clocks disabled

(4) See 表 6-2 for a detailed description of peripherals in high-frequency, low-frequency, or unlocked state.

(5) See 节 6.3.1, which describes the use of peripherals in LPM3 and LPM4.

(6) Controlled by SMCLKOFF

(7) Using the RAM controller, the RAM can be completely powered down to save leakage; however, all data are lost.

(8) Activated SVS (SVSHE = 1) results in higher current consumption. SVS is not included in typical current consumption.

(9) SVSHE = 1

(10) SVSHE = 0

### 6.3.1 Peripherals in Low-Power Modes

Peripherals can be in different states that impact the achievable power modes of the device. The states depend on the operational modes of the peripherals (see 表 6-2). The states are:

- A peripheral is in a *high-frequency state* if it requires or uses a clock with a "high" frequency of more than 50 kHz.
- A peripheral is in a *low-frequency state* if it requires or uses a clock with a "low" frequency of 50 kHz or less.
- A peripheral is in an *unclocked state* if it does not require or use an internal clock.

If the CPU requests a power mode that does not support the current state of all active peripherals, the device does not enter the requested power mode and instead enters a power mode that still supports the current state of the peripherals, unless an external clock is used. If an external clock is used, the application must ensure that the correct frequency range for the requested power mode is selected.

**表 6-2. Peripheral States**

(1) Peripherals are in a state that requires or uses a clock with a "high" frequency of more than 50 kHz.

(2) Peripherals are in a state that requires or uses a clock with a "low" frequency of 50 kHz or less.

(3) Peripherals are in a state that does not require or does not use an internal clock.

(4) The DMA always transfers data in active mode but can wait for a trigger in any low-power mode. A DMA trigger during a low-power mode will cause a temporary transition into active mode for the time of the transfer.

(5) Operates only during active mode and will delay the transition into a low-power mode until its operation is completed.

### 6.3.1.1 Idle Currents of Peripherals in LPM3 and LPM4

Most peripherals can be activated to be operational in LPM3 if clocked by ACLK. Some modules are even operational in LPM4 because they do not require a clock to operate (for example, the comparator). Activating a peripheral in LPM3 or LPM4 increases the current consumption due to its active supply current contribution but also due to an additional idle current. To limit the idle current adder certain peripherals are group together. To achieve optimal current consumption try to use modules within one group and to limit the number of groups with active modules. 表 6-3 lists the group for each peripheral. Modules not listed in this table are either already included in the standard LPM3 current consumption specifications or cannot be used in LPM3 or LPM4.

The idle current adder is very small at room temperature (25°C) but increases at high temperatures (85°C). See the  $I_{IDLE}$  parameters in Section 5.7 for details.

## 6.4 Interrupt Vector Table and Signatures

The interrupt vectors, the power-up start address and signatures are in the address range 0FFFFh to 0FF80h. 图 6-1 summarizes the content of this address range.

图 6-1. Interrupt Vectors, Signatures, and Passwords

The power-up start address or reset vector is located at 0FFFFh to 0FFFEh. It contains the 16-bit address pointing to the start address of the application program.

The interrupt vectors start at 0FFFDh and extend to lower addresses. Each vector contains the 16-bit address of the appropriate interrupt-handler instruction sequence. 表 6-4 shows the device-specific interrupt vector locations.

The vectors programmed into the address range from 0FFFFh to 0FFE0h are used as the BSL password (if enabled by the corresponding signature).

The signatures are located at 0FF80h and extend to higher addresses. Signatures are evaluated during device start-up. 表 6-5 shows the device-specific signature locations.

A JTAG password can be programmed starting at address 0FF88h and extending to higher addresses. The password can extend into the interrupt vector locations using the interrupt vector addresses as additional bits for the password. The length of the JTAG password depends on the JTAG signature.

See the *System Resets, Interrupts, and Operating Modes, System Control Module (SYS)* chapter in the [MSP430FR58xx, MSP430FR59xx, MSP430FR68xx, MSP430FR69xx Family User's Guide](#) for details.

## 6.5 Bootloader (BSL)

The BSL enables programming of the FRAM or RAM using a UART serial interface (FRxxxx devices) or an I<sup>2</sup>C interface (FRxxxx1 devices). Access to the device memory through the BSL is protected by a user-defined password. 表 6-6 lists the BSL pin requirements. BSL entry requires a specific entry sequence on the  $\overline{\text{RST}}/\text{NMI}/\text{SBWTDIO}$  and TEST/SBWTCCK pins. For complete description of the features of the BSL and its implementation, see [MSP430 Programming With the Bootloader \(BSL\)](#).

## 6.6 JTAG Operation

### 6.6.1 JTAG Standard Interface

The MSP430 family supports the standard JTAG interface, which requires four signals for sending and receiving data. The JTAG signals are shared with general-purpose I/Os. The TEST/SBWTCCK pin is used to enable the JTAG signals. In addition to these signals, the  $\overline{\text{RST}}/\text{NMI}/\text{SBWTDIO}$  signal is required to interface with MSP430 development tools and device programmers. 表 6-7 lists the JTAG pin requirements. For details on interfacing to development tools and device programmers, see the [MSP430 Hardware Tools User's Guide](#). For details on the JTAG implementation in MSP MCUs, see [MSP430 Programming With the JTAG Interface](#).

### 6.6.2 Spy-Bi-Wire Interface

In addition to the standard JTAG interface, the MSP430 family supports the 2-wire Spy-Bi-Wire interface. Spy-Bi-Wire can be used to interface with MSP430 development tools and device programmers. 表 6-8 lists the Spy-Bi-Wire interface pin requirements. For details on interfacing to development tools and device programmers, see the [MSP430 Hardware Tools User's Guide](#). For details on the SBW implementation in MSP MCUs, see [MSP430 Programming With the JTAG Interface](#).

## 6.7 FRAM

The FRAM can be programmed through the JTAG port, Spy-Bi-Wire (SBW), the BSL, or in system by the CPU. Features of the FRAM include:

- Ultra-low-power ultra-fast-write nonvolatile memory
- Byte and word access capability
- Programmable wait state generation
- Error correction coding (ECC)

### 注

#### Wait States

For MCLK frequencies > 8 MHz, wait states must be configured following the flow described in the "FRAM Controller (FRCTRL)" chapter, section "Wait State Control" of the [MSP430FR58xx, MSP430FR59xx, MSP430FR68xx, MSP430FR69xx Family User's Guide](#).

For important software design information regarding FRAM including but not limited to partitioning the memory layout according to application-specific code, constant, and data space requirements, the use of FRAM to optimize application energy consumption, and the use of the memory protection unit (MPU) to maximize application robustness by protecting the program code against unintended write accesses, see [MSP430 FRAM Technology – How To and Best Practices](#).

## 6.8 RAM

The RAM is made up of one sector. The sector can be completely powered down in LPM3 and LPM4 to save leakage; however, all data is lost during shutdown.

## 6.9 Tiny RAM

The Tiny RAM can be used to hold data or a very small stack if the complete RAM is powered down in LPM3 and LPM4.

## 6.10 Memory Protection Unit Including IP Encapsulation

The FRAM can be protected from inadvertent CPU execution, read or write access by the MPU. Features of the MPU include:

- IP Encapsulation with programmable boundaries (prevents reads from "outside" like JTAG or non-IP software) in steps of 1KB.
- Main memory partitioning programmable up to three segments in steps of 1KB.
- The access rights of each segment (main and information memory) can be individually selected.
- Access violation flags with interrupt capability for easy servicing of access violations.

## 6.11 Peripherals

Peripherals are connected to the CPU through data, address, and control buses. Peripherals can be managed using all instructions. For complete module descriptions, see the [MSP430FR58xx](#), [MSP430FR59xx](#), [MSP430FR68xx](#), [MSP430FR69xx Family User's Guide](#).

### 6.11.1 Digital I/O

Up to eleven 8-bit I/O ports are implemented:

- All individual I/O bits are independently programmable.
- Any combination of input, output, and interrupt conditions is possible.
- Programmable pullup or pulldown on all ports.
- Edge-selectable interrupt and LPM3.5 and LPM4.5 wake-up input capability is available for all pins of ports P1, P2, P3, and P4.
- Read and write access to port-control registers is supported by all instructions.
- Ports can be accessed byte-wise or word-wise in pairs.
- Capacitive touch functionality is supported on all pins of ports P1 to P10 and PJ.
- No cross-currents during start-up

#### 注

##### Configuration of Digital I/Os After BOR Reset

To prevent any cross-currents during start-up of the device all port pins are high-impedance with Schmitt triggers and their module functions disabled. To enable the I/O functionality after a BOR reset the ports must be configured first and then the LOCKLPM5 bit must be cleared. For details, see the *Configuration After Reset* section of the *Digital I/O* chapter in the [MSP430FR58xx](#), [MSP430FR59xx](#), [MSP430FR68xx](#), [MSP430FR69xx Family User's Guide](#).

### 6.11.2 Oscillator and Clock System (CS)

The clock system includes support for a 32-kHz watch crystal oscillator XT1 (LF), an internal very-low-power low-frequency oscillator (VLO), an integrated internal digitally controlled oscillator (DCO), and a high-frequency crystal oscillator XT2 (HF). The clock system module is designed to meet the requirements of both low system cost and low power consumption. A fail-safe mechanism exists for all crystal sources. The clock system module provides the following clock signals:

- Auxiliary clock (ACLK), sourced from a 32-kHz watch crystal (LFXT1), the internal low-frequency oscillator (VLO), or a digital external low frequency (<50 kHz) clock source.
- Main clock (MCLK), the system clock used by the CPU. MCLK can be sourced from a high-frequency crystal (HFXT2), the internal digitally controlled oscillator DCO, a 32-kHz watch crystal (LFXT1), the internal low-frequency oscillator (VLO), or a digital external clock source.
- Sub-Main clock (SMCLK), the subsystem clock used by the peripheral modules. SMCLK can be sourced by same sources made available to MCLK.

### 6.11.3 Power-Management Module (PMM)

The primary functions of the PMM are:

- Supply regulated voltages to the core logic
- Supervise voltages that are connected to the device (at DVCC pins)
- Give reset signals to the device during power on and power off

#### 6.11.4 Hardware Multiplier (MPY)

The multiplication operation is supported by a dedicated peripheral module. The module performs operations with 32-, 24-, 16-, and 8-bit operands. The module supports signed and unsigned multiplication as well as signed and unsigned multiply-and-accumulate operations.

#### 6.11.5 Real-Time Clock (RTC\_C)

The RTC\_C module contains an integrated real-time clock (RTC) with the following features implemented:

- Calendar mode with leap year correction
- General-purpose counter mode

The internal calendar compensates months with less than 31 days and includes leap year correction. The RTC\_C also supports flexible alarm functions and offset-calibration hardware. RTC operation is available in LPM3.5 modes to minimize power consumption.

#### 6.11.6 Watchdog Timer (WDT\_A)

The primary function of the WDT\_A module is to perform a controlled system restart after a software problem occurs. If the selected time interval expires, a system reset is generated. If the watchdog function is not needed in an application, the module can be configured as an interval timer and can generate interrupts at selected time intervals. 表 6-9 lists the clocks that can be used by the WDT.

#### 注

In watchdog mode, the watchdog timer prevents entry into LPM3.5 or LPM4.5 because this would deactivate the watchdog.

表 6-9. WDT\_A Clocks

WDTSEL	NORMAL OPERATION (WATCHDOG AND INTERVAL TIMER MODE)
00	SMCLK
01	ACLK

#### 6.11.7 System Module (SYS)

The SYS module handles many of the system functions within the device. These system functions include power-on reset and power-up clear handling, NMI source selection and management, reset interrupt vector generators, bootloader entry mechanisms, and configuration management (device descriptors). The SYS module also includes a data exchange mechanism through JTAG called a JTAG mailbox that can be used in the application. 表 6-10 lists the interrupt vector registers of the SYS module.

### 6.11.8 DMA Controller

The DMA controller allows movement of data from one memory address to another without CPU intervention. For example, the DMA controller can be used to move data from the ADC10\_B conversion memory to RAM. Using the DMA controller can increase the throughput of peripheral modules. The DMA controller reduces system power consumption by allowing the CPU to remain in sleep mode, without having to awaken to move data to or from a peripheral. 表 6-11 lists the triggers that can be used to start DMA operation.

### 6.11.15 ADC12\_B

The ADC12\_B module supports fast 12-bit analog-to-digital conversions with differential and single-ended inputs. The module implements a 12-bit SAR core, sample select control, a reference generator, and a conversion result buffer. A window comparator with lower and upper limits allows CPU-independent result monitoring with three window comparator interrupt flags.

表 6-17 lists the external trigger sources. 表 6-18 lists the available multiplexing between internal and external analog inputs.

### 6.11.16 Comparator\_E

The primary function of the Comparator\_E module is to support precision slope analog-to-digital conversions, battery voltage supervision, and monitoring of external analog signals.

### 6.11.17 CRC16

The CRC16 module produces a signature based on a sequence of entered data values and can be used for data checking purposes. The CRC16 signature is based on the CRC-CCITT standard.

### 6.11.18 CRC32

The CRC32 module produces a signature based on a sequence of entered data values and can be used for data checking purposes. The CRC32 signature is based on the ISO 3309 standard.

### 6.11.19 AES256 Accelerator

The AES accelerator module performs encryption and decryption of 128-bit data with 128-, 192-, or 256-bit keys according to the Advanced Encryption Standard (AES) (FIPS PUB 197) in hardware.

### 6.11.20 True Random Seed

The Device Descriptor Information (TLV) section contains a 128-bit true random seed that can be used to implement a deterministic random number generator.

### 6.11.21 Shared Reference (REF\_A)

The reference module (REF\_A) generates all critical reference voltages that can be used by the various analog peripherals in the device.

### 6.11.22 LCD\_C

The LCD\_C driver generates the segment and common signals required to drive a liquid crystal display (LCD). The LCD\_C controller has dedicated data memories to hold segment drive information. Common and segment signals are generated as defined by the mode. Static and 2-mux to 8-mux LCDs are supported. The module can provide a LCD voltage independent of the supply voltage with its integrated charge pump. It is possible to control the level of the LCD voltage and thus contrast by software. The module also provides an automatic blinking capability for individual segments in static, 2-mux, 3-mux, and 4-mux modes.

To reduce system noise, the charge pump can be temporarily disabled. 表 6-19 lists the available automatic charge pump disable options.

**表 6-19. LCD Automatic Charge Pump Disable Bits (LCDCPDISx)**

(2) Setting P8SEL1.x and P8SEL0.x disables the output driver and the input Schmitt trigger to prevent parasitic cross currents when applying analog signals.

(3) Setting the CEPD.x bit of the comparator disables the output driver and the input Schmitt trigger to prevent parasitic cross currents when applying analog signals. Selecting the Cx input pin to the comparator multiplexer with the input select bits in the comparator module automatically disables output driver and input buffer for that pin, regardless of the state of the associated CEPD.x bit.

(3) ADC offset: The offset correction factor is measured using the internal 2.5-V reference.

## 7 Applications, Implementation, and Layout

### 注

Information in the following applications sections is not part of the TI component specification, and TI does not warrant its accuracy or completeness. TI's customers are responsible for determining suitability of components for their purposes. Customers should validate and test their design implementation to confirm system functionality.

### 7.1 Device Connection and Layout Fundamentals

This section discusses the recommended guidelines when designing with the MSP430. These guidelines are to make sure that the device has proper connections for powering, programming, debugging, and optimum analog performance.

#### 7.1.1 Power Supply Decoupling and Bulk Capacitors

TI recommends connecting a combination of a 1- $\mu$ F plus a 100-nF low-ESR ceramic decoupling capacitor to each AVCC, DVCC, and ESIDVCC pin. Higher-value capacitors may be used but can impact supply rail ramp-up time. Decoupling capacitors must be placed as close as possible to the pins that they decouple (within a few millimeters). Additionally, TI recommends separated grounds with a single-point connection for better noise isolation from digital to analog circuits on the board and to achieve high analog accuracy.

图 7-1. Power Supply Decoupling

#### 7.1.2 External Oscillator

Depending on the device variant (see [Section 3](#)), the device can support a low-frequency crystal (32 kHz) on the LFX pins, a high-frequency crystal on the HFXT pins, or both. External bypass capacitors for the crystal oscillator pins are required.

It is also possible to apply digital clock signals to the LFXIN and HFXIN input pins that meet the specifications of the respective oscillator if the appropriate LFXTBYPASS or HFXTBYPASS mode is selected. In this case, the associated LFXOUT and HFXOUT pins can be used for other purposes. If they are left unused, terminate them according to [Section 4.4](#).

图 7-2 shows a typical connection diagram.

图 7-2. Typical Crystal Connection

See [MSP430 32-kHz Crystal Oscillators](#) for more information on selecting, testing, and designing a crystal oscillator with the MSP430 devices.

### 7.1.3 JTAG

With the proper connections, the debugger and a hardware JTAG interface (such as the MSP-FET or MSP-FET430UIF) can be used to program and debug code on the target board. In addition, the connections also support the MSP-GANG production programmers, thus providing an easy way to program prototype boards, if desired. 图 7-3 shows the connections between the 14-pin JTAG connector and the target device required to support in-system programming and debugging for 4-wire JTAG communication. 图 7-4 shows the connections for 2-wire JTAG mode (Spy-Bi-Wire).

The connections for the MSP-FET and MSP-FET430UIF interface modules and the MSP-GANG are identical. Both can supply VCC to the target board (through pin 2). In addition, the MSP-FET and MSP-FET430UIF interface modules and MSP-GANG have a VCC sense feature that, if used, requires an alternate connection (pin 4 instead of pin 2). The VCC-sense feature senses the local VCC present on the target board (that is, a battery or other local power supply) and adjusts the output signals accordingly. 图 7-3 and 图 7-4 show a jumper block that supports both scenarios of supplying VCC to the target board. If this flexibility is not required, the desired VCC connections may be hard-wired to eliminate the jumper block. Pins 2 and 4 must not be connected at the same time.

For additional design information regarding the JTAG interface, see the [MSP430 Hardware Tools User's Guide](#).

The upper limit for C1 is 2.2 nF when using current TI tools.

图 7-4. Signal Connections for 2-Wire JTAG Communication (Spy-Bi-Wire)

### 7.1.4 Reset

The reset pin can be configured as a reset function (default) or as an NMI function in the Special Function Register (SFR), SFRPCR.

In reset mode, the  $\overline{\text{RST}}/\text{NMI}$  pin is active low, and a pulse applied to this pin that meets the reset timing specifications generates a BOR-type device reset.

Setting SYSNMI causes the  $\overline{\text{RST}}/\text{NMI}$  pin to be configured as an external NMI source. The external NMI is edge sensitive, and its edge is selectable by SYSNMIIES. Setting the NMIIE enables the interrupt of the external NMI. When an external NMI event occurs, the NMIIFG is set.

The  $\overline{\text{RST}}/\text{NMI}$  pin can have either a pullup or pulldown that is enabled or not. SYSRSTUP selects either pullup or pulldown, and SYSRSTRE causes the pullup (default) or pulldown to be enabled (default) or not. If the  $\overline{\text{RST}}/\text{NMI}$  pin is unused, it is required either to select and enable the internal pullup or to connect an external 47-kΩ pullup resistor to the  $\overline{\text{RST}}/\text{NMI}$  pin with a 2.2-nF pulldown capacitor. The pulldown capacitor should not exceed 2.2 nF when using devices in Spy-Bi-Wire mode or in 4-wire JTAG mode with TI tools like FET interfaces or GANG programmers. If JTAG or Spy-Bi-Wire access is not needed, up to a 10-nF pulldown capacitor may be used.

See the [MSP430FR58xx](#), [MSP430FR59xx](#), [MSP430FR68xx](#), and [MSP430FR69xx Family User's Guide](#) for more information on the referenced control registers and bits.

### 7.1.5 Unused Pins

For details on the connection of unused pins, see [Section 4.4](#).

### 7.1.6 General Layout Recommendations

- Proper grounding and short traces for external crystal to reduce parasitic capacitance. See [MSP430 32-kHz Crystal Oscillators](#) for recommended layout guidelines.
- Proper bypass capacitors on DVCC, AVCC, and reference pins if used.
- Avoid routing any high-frequency signal close to an analog signal line. For example, keep digital switching signals such as PWM or JTAG signals away from the oscillator circuit.
- See [Circuit Board Layout Techniques](#) for a detailed discussion of PCB layout considerations. This document is written primarily about op amps, but the guidelines are generally applicable for all mixed-signal applications.
- Proper ESD level protection should be considered to protect the device from unintended high-voltage electrostatic discharge. See [MSP430 System-Level ESD Considerations](#) for guidelines.

### 7.1.7 Do's and Don'ts

TI recommends powering the AVCC, DVCC, and ESIDVCC pins from the same source. At a minimum, during power up, power down, and device operation, the voltage difference between AVCC and DVCC must not exceed the limits specified in the [Absolute Maximum Ratings](#) section. Exceeding the specified limits may cause malfunction of the device including erroneous writes to RAM and FRAM.

## 7.2 Peripheral- and Interface-Specific Design Information

### 7.2.1 ADC12\_B Peripheral

#### 7.2.1.1 Partial Schematic

图 7-5 shows the recommended decoupling circuit when an external voltage reference is used.

图 7-5. ADC12\_B Grounding and Noise Considerations

#### 7.2.1.2 Design Requirements

As with any high-resolution ADC, appropriate printed-circuit-board layout and grounding techniques should be followed to eliminate ground loops, unwanted parasitic effects, and noise.

Ground loops are formed when return current from the ADC flows through paths that are common with other analog or digital circuitry. If care is not taken, this current can generate small unwanted offset voltages that can add to or subtract from the reference or input voltages of the ADC. The general guidelines in 节 7.1.1 combined with the connections shown in 节 7.2.1.1 prevent this.

In addition to grounding, ripple and noise spikes on the power-supply lines that are caused by digital switching or switching power supplies can corrupt the conversion result. A noise-free design using separate analog and digital ground planes with a single-point connection is recommend to achieve high accuracy.

图 7-5 shows the recommended decoupling circuit when an external voltage reference is used. The internal reference module has a maximum drive current as specified in the Reference module's  $I_{O(VREF+)}$  specification.

The reference voltage must be a stable voltage for accurate measurements. The capacitor values that are selected in the general guidelines filter out the high- and low-frequency ripple before the reference voltage enters the device. In this case, the 10- $\mu$ F capacitor is used to buffer the reference pin and filter any low-frequency ripple. A bypass capacitor of 4.7  $\mu$ F is used to filter out any high-frequency noise.

### 7.2.1.3 Detailed Design Procedure

For additional design information, see [Designing With the MSP430FR58xx, FR59xx, FR68xx, and FR69xx ADC](#).

### 7.2.1.4 Layout Guidelines

Component that are shown in the partial schematic (see 图 7-5) should be placed as close as possible to the respective device pins. Avoid long traces, because they add additional parasitic capacitance, inductance, and resistance on the signal.

Avoid routing analog input signals close to a high-frequency pin (for example, a high-frequency PWM), because the high-frequency switching can be coupled into the analog signal.

If differential mode is used for the ADC12\_B, the analog differential input signals must be routed closely together to minimize the effect of noise on the resulting signal.

## 7.2.2 LCD\_C Peripheral

### 7.2.2.1 Partial Schematic

Required LCD connections greatly vary by the type of display that is used (static or multiplexed), whether external or internal biasing is used, and also whether the on-chip charge pump is employed. For any display used, there is flexibility as to how the segment (Sx) and common (COMx) signals are connected to the MCU, which (assuming that the correct choices are made) can be advantageous for the PCB layout and for the design of the application software.

Because LCD connections are application specific, it is difficult to provide a single one-fits-all schematic. However, for an example of connecting a 4-mux LCD with 40 segment lines that has a total of  $4 \times 40 = 160$  individually addressable LCD segments to an MSP430FR6989, see the [Water Meter Reference Design for Two LC Sensors, Using Extended Scan Interface \(ESI\)](#).

### 7.2.2.2 Design Requirements

Due to the flexibility of the LCD\_C peripheral module to accommodate various segment-based LCDs, selecting the correct display for the application in combination with determining specific design requirements is often an iterative process. There can be well defined requirements in terms of how many individually addressable LCD segments need to be controlled, what the requirements for LCD contrast are, which device pins are available for LCD use, and which are required by other application functions, and what the power budget is, to name just a few. TI recommends reviewing the LCD\_C peripheral module chapter in the [MSP430FR58xx, MSP430FR59xx, MSP430FR68xx, and MSP430FR69xx Family User's Guide](#) during the initial design requirements and decision process. 表 7-1 is a brief overview over different choices that can be made and their effects.

**表 7-1. LCD Features and Use Cases**

### 7.2.2.3 Detailed Design Procedure

A major component in designing the LCD solution is determining the exact connections between the LCD\_C peripheral module and the display itself. Two basic design processes can be employed for this step, although in reality often a balanced co-design approach is recommended:

- PCB layout-driven design
- Software-driven design

In the PCB layout-driven design process, the segment Sx and common COMx signals are connected to respective MSP430 device pins so that the routing of the PCB can be optimized to minimize signal crossings and to keep signals on one side of the PCB only, typically the top layer. For example, using a multiplexed LCD, it is possible to arbitrarily connect the Sx and COMx signals between the LCD and the MSP430 device as long as segment lines are swapped with segment lines and common lines are swapped with common lines. It is also possible to not contiguously connect all segment lines but rather skip LCD\_C module segment connections to optimize layout or to allow access to other functions that may be multiplexed on a particular device port pin. Employing a purely layout-driven design approach, however, can result in the LCD\_C module control bits that are responsible for turning on and off segments to appear scattered throughout the memory map of the LCD controller (LCDMx registers). This approach potentially places a rather large burden on the software design that may also result in increased energy consumption due to the computational overhead required to work with the LCD.

The other extreme is a purely software-driven approach that starts with the idea that control bits for LCD segments that are frequently turned on and off together should be co-located in memory in the same LCDMx register or in adjacent registers. For example, in case of a 4-mux display that contains several 7-segment digits, from a software perspective it can be very desirable to control all 7 segments of each digit through a single byte-wide access to an LCDMx register. And consecutive segments are mapped to consecutive LCDMx registers. This allows use of simple look-up tables or software loops to output numbers on an LCD, reducing computational overhead and optimizing the energy consumption of an application. Establishing of the most convenient memory layout needs to be performed in conjunction with the specific LCD that is being used to understand its design constraints in terms of which segment and which common signals are connected to, for example, a digit.

For design information regarding the LCD controller input voltage selection including internal and external options, contrast control, and bias generation, see the *LCD\_C Controller* chapter in the [MSP430FR58xx, MSP430FR59xx, MSP430FR68xx, and MSP430FR69xx Family User's Guide](#).

For additional design information, see [Designing With MSP430 and Segment LCDs](#).

### 7.2.2.4 Layout Guidelines

LCD segment (Sx) and common (COMx) signal traces are continuously switching while the LCD is enabled and should, therefore, be kept away from sensitive analog signals such as ADC inputs to prevent any noise coupling. TI recommends keeping the LCD signal traces on one side of the PCB grouped together in a bus-like fashion. A ground plane underneath the LCD traces and guard traces employed alongside the LCD traces can provide shielding.

If the internal charge pump of the LCD module is used, the externally provided capacitor on the LCDCAP pin should be located as close as possible to the MCU. The capacitor should be connected to the device using a short and direct trace and also have a solid connection to the ground plane that is supplying the V<sub>SS</sub> pins of the MCU.

For an example layout of connecting a 4-mux LCD with 40 segments to an MSP430FR6989 and using the charge pump feature, see the [Water Meter Reference Design for Two LC Sensors, Using Extended Scan Interface \(ESI\)](#).

## 7.2.3 Extended Scan Interface (ESI) Peripheral

### 7.2.3.1 Overview

The external connections for using the Extended Scan Interface (ESI) peripheral module depend on the ESI operating mode and the application details. For example, using the ESI in conjunction with analog LC sensors requires different connections than using the ESI with resistive sensors. Also, using optical sensors and encoders that have a digital output require different considerations.

表 7-2 lists reference designs that use the ESI to interface with different types of sensors to perform rotation detection. These reference designs provide the hardware and software design files as well as analysis and user's guides to jumpstart your microcontroller-based projects.

### 7.2.3.2 Design Requirements

The hardware design requirements are specific to the use case and are most affected by the specification of the interaction of the chosen analog or digital sensors with the analog front ends (AFE1 and AFE2) of the ESI. However, when designing the sensor circuit, the other digital parts of the ESI module, namely the preprocessing unit (PPU), the processing state machine (PSM) with its associated RAM, the timing state machine (TSM), and the Timer\_A output stage must also be considered to ensure that the processing as required by the application can be performed in an autonomous manner inside the ESI. See the *Extended Scan Interface (ESI)* chapter of the [MSP430FR58xx, MSP430FR59xx, MSP430FR68xx, and MSP430FR69xx Family User's Guide](#) for additional information regarding the design requirements and constraints of the module.

### 7.2.3.3 Detailed Design Procedure

TI provides a variety of collateral to aid the design and implementation of the ESI into specific applications, most of which are related to metering. The following application notes are available as of this writing. Additional application notes may be available in the device-specific product folder.

For complete and fully documented reference implementations that use the ESI to interface with different types of sensors to perform rotation detection, see 表 7-2.

#### 7.2.3.4 Layout Guidelines

The proper operation of the ESI and the connected sensor front end relies on a good analog board layout. Specifically in case of using the ESI analog front ends to interface with LC type or resistive sensors as typically employed in metering applications, the designer must make sure that the sensitive analog sensor signals are kept separated and guarded from any noise that might occur in the system including but not limited to the switching of LCD segment and common lines, communication signals, or any other type of digital I/O that is toggling. Failure to follow proper precautions may reduce the sensitivity of the solution or may render the application inoperable.

Customers are encouraged to study and follow one of the available TI Designs (see [表 7-2](#)) for additional guidance. Also see [节 7.1.6](#) for more information that is applicable to this topic.

<sup>(1)</sup> The marketing status values are defined as follows:

**ACTIVE:** Product device recommended for new designs.

**LIFEBUY:** TI has announced that the device will be discontinued, and a lifetime-buy period is in effect.

**NRND:** Not recommended for new designs. Device is in production to support existing customers, but TI does not recommend using this part in a new design.

**PREVIEW:** Device has been announced but is not in production. Samples may or may not be available.

**OBSOLETE:** TI has discontinued the production of the device.

<sup>(2)</sup> Eco Plan - The planned eco-friendly classification: Pb-Free (RoHS), Pb-Free (RoHS Exempt), or Green (RoHS & no Sb/Br) - please check <http://www.ti.com/productcontent> for the latest availability information and additional product content details.

**TBD:** The Pb-Free/Green conversion plan has not been defined.

**Pb-Free (RoHS):** TI's terms "Lead-Free" or "Pb-Free" mean semiconductor products that are compatible with the current RoHS requirements for all 6 substances, including the requirement that lead not exceed 0.1% by weight in homogeneous materials. Where designed to be soldered at high temperatures, TI Pb-Free products are suitable for use in specified lead-free processes.

**Pb-Free (RoHS Exempt):** This component has a RoHS exemption for either 1) lead-based flip-chip solder bumps used between the die and package, or 2) lead-based die adhesive used between the die and leadframe. The component is otherwise considered Pb-Free (RoHS compatible) as defined above.

**Green (RoHS & no Sb/Br):** TI defines "Green" to mean Pb-Free (RoHS compatible), and free of Bromine (Br) and Antimony (Sb) based flame retardants (Br or Sb do not exceed 0.1% by weight in homogeneous material)

<sup>(3)</sup> MSL, Peak Temp. - The Moisture Sensitivity Level rating according to the JEDEC industry standard classifications, and peak solder temperature.

<sup>(4)</sup> There may be additional marking, which relates to the logo, the lot trace code information, or the environmental category on the device.

<sup>(5)</sup> Multiple Device Markings will be inside parentheses. Only one Device Marking contained in parentheses and separated by a "~" will appear on a device. If a line is indented then it is a continuation of the previous line and the two combined represent the entire Device Marking for that device.

<sup>(6)</sup> Lead/Ball Finish - Orderable Devices may have multiple material finish options. Finish options are separated by a vertical ruled line. Lead/Ball Finish values may wrap to two lines if the finish value exceeds the maximum column width.

PLASTIC QUAD FLATPACK NO-LEAD

### THERMAL INFORMATION

This package incorporates an exposed thermal pad that is designed to be attached directly to an external heatsink. The thermal pad must be soldered directly to the printed circuit board (PCB). After soldering, the PCB can be used as a heatsink. In addition, through the use of thermal vias, the thermal pad can be attached directly to the appropriate copper plane shown in the electrical schematic for the device, or alternatively, can be attached to a special heatsink structure designed into the PCB. This design optimizes the heat transfer from the integrated circuit (IC).

For information on the Quad Flatpack No-Lead (QFN) package and its advantages, refer to Application Report, QFN/SON PCB Attachment, Texas Instruments Literature No. SLUA271. This document is available at [www.ti.com](http://www.ti.com).

The exposed thermal pad dimensions for this package are shown in the following illustration.
